October 2011

**Pacific Salmon Commission
Technical Report No. 27**

The Pacific Salmon Commission is charged with the implementation of the Pacific Salmon Treaty, which was signed by Canada and the United States in 1985. The focus of the agreement are salmon stocks that originate in one country and are subject to interception by the other country. The objectives of the Treaty are to 1) conserve the five species of Pacific salmon in order to achieve optimum production, and 2) to divide the harvests so each country reaps the benefits of its investment in salmon management.

Technical Reports of the Pacific Salmon Commission present results of completed or ongoing investigations carried out by the Pacific Salmon Commission that are deemed of sufficient interest to be made available to the scientific community and the public.

The contents of these reports may be reprinted, and reference to the source will be appreciated.

ACKNOWLEDGMENTS

This project was conducted co-operatively by the Alaska Department of Fish and Game (ADF&G), the Department of Fisheries and Oceans Canada (DFO), and the Taku River Tlingit First Nation (TRTFN). The authors would like to express their appreciation to the staff at the Canyon Island fish wheels: Mike LaFollette, Ben Heermans, Dave Dreyer(ADF&G) as well as Mike Smarch and Joey Jack (TRTFN); and to the crew stationed at the lower Taku River: Patrick Jackson, Lars Jessup, Kirstie Falkevitch, Mike Lake and Mathieu Ducharme (DFO) for collecting fishery statistics and applying spaghetti tags. We would also like to thank Canadian commercial fishers, United States personal use and commercial gillnet fishers, as well as Brian Mercer, Harry Carlick, and other individuals working on spawning escapement projects, for recovering spaghetti tags. Thanks also to Mark Connor for supervising TRTFN field operations; and Penny Saddler for managing Canyon Island data, providing inseason run status updates, as well as assisting with several tables and figures used in this report. We would also like to thank Mark Olsen (ADF&G) for his efforts in running the Canyon Island AWL forms through the OPSCAN machine, Steve Parker (DFO) and Clyde Andrews (ADF&G) for expediting.

ABSTRACT

Mark recapture studies of adult Taku River salmon *Oncorhynchus* stocks were conducted by the Department of Fisheries and Oceans Canada, the Alaska Department of Fish and Game, and the Taku River Tlingit First Nation in 2007. The objectives of the studies were to provide inseason estimates of the inriver abundance of sockeye *O. nerka* and to document biological characteristics (migratory timing, migratory rates and age, sex, and size composition) of Taku River sockeye stocks. Tagged-to-untagged ratios of salmon harvested in the Canadian inriver gillnet fisheries were used to develop the estimates of the inriver abundance of sockeye. A total of 7,664 sockeye salmon were captured in fish wheels located at Canyon Island, Alaska, of which 7,055 were tagged and 2,183 (32.0%) were subsequently recovered or observed in fisheries or on the spawning grounds. The inriver run of sockeye salmon past Canyon Island from June 10 to September 22 was estimated to be 104,815 fish (95% confidence interval 97,171 to 112,444). An expansion factor based on fish wheel CPUE estimated 197 additional sockeye salmon migrated past Canyon Island prior to and after June 10 to September 22, for a total above border escapement of 105,012. Canadian commercial, test, and aboriginal fisheries harvested 16,714, 376 and 159 sockeye respectively, resulting in a spawning escapement estimate of 87,604 sockeye salmon. Based on mean date and standard deviation of migration timing the sockeye salmon run was over one week late and more compressed than the 1984-2006 average. Based on tag recoveries, the majority of the Little Trapper Lake stock passed Canyon Island earlier than the Tatsamenie Lake stock; a lack of recoveries, due to high water levels at Kuthai Lake and King Salmon weirs, did not allow for stock timing comparisons for these stocks. The Canyon Island catches of 12,405 pink salmon, 462 chum salmon and 63 steelhead salmon were 7.8% below average, 48.7% above average and 45.6% below average, respectively. The pink salmon run was six days later and slightly less compressed than average.

KEY WORDS: mark-recapture, stratified population estimations, escapement estimation, migratory timing, Taku River, transboundary river, salmon, fish wheel, age, length and sex composition, Pacific Salmon Treaty

INTRODUCTION

Inseason estimates of the spawning escapement of Taku River sockeye *Oncorhynchus nerka* are needed to fulfill the escapement goal and international harvest sharing requirements for stocks specified by the U.S./Canada Pacific Salmon Treaty. The Taku River mark-recapture project has been conducted annually since 1984 (Clark et al. 1986; McGregor and Clark 1987, 1988, 1989; McGregor et al. 1991; Kelley and Milligan 1999; Andel and Boyce 2006) as a joint U.S./Canada program involving the Alaska Department of Fish and Game (ADF&G) and the Department of Fisheries and Oceans Canada (DFO) to provide weekly estimates of the Taku River salmon escapement past Canyon Island, Alaska (Figure 1). The Taku River Tlingit First Nation (TRTFN) began providing a technician to assist with operations in 1994. U.S. and Canadian fishery managers use CPUE and stock composition data from the U.S. District 111 and Canadian Taku River commercial gillnet fisheries and escapement estimates from this project to adjust fishing times, catches, and escapements.

The Taku River is a transboundary river which originates in northern British Columbia and flows southwest through the Coastal Mountain Range and Southeast Alaska to the Pacific Ocean (Figure 1). The Taku River supports numerous stocks of salmon that are harvested by Canadian and U.S. gillnet fisheries. The Canadian fishery, which occurs inriver, targets Taku River chinook¹, sockeye and coho salmon and incidentally harvests chinook and pink salmon. The U.S. drift gillnet fishery which occurs in Taku Inlet and approach waters, primarily targets Taku River chinook and sockeye salmon stocks as well as summer chum salmon from local Alaskan enhancement programs during the summer months and mixed stocks of coho in fall. The U.S. fishery also incidentally harvests chinook and pink salmon. The Canada/U.S. Pacific Salmon Treaty (PST) of 1985, and subsequent additions to the original treaty, established conservation (71,000 to 80,000 escapement goal) and harvest sharing (percentage sharing of the allowable catch) objectives for the Taku River sockeye salmon run. The PST mandates cooperative international management of transboundary river stocks. The most intensive cooperative management is directed at sockeye, coho, and chinook salmon.

Mark-recapture methods were used in 2007 to estimate sockeye, chinook and coho salmon escapements. Chinook and coho studies are described in separate reports published by the ADF&G Division of Sport Fish and the Pacific Salmon Commission (in prep.) Fish wheels located at Canyon Island were used to capture sockeye, chinook, and coho for tagging. Tagging data coupled with ratios of tagged to untagged fish in the Canadian fisheries upstream were used to develop escapement estimates inseason.

The fish wheels also catch pink, chum and steelhead salmon. Although abundance is not estimated, the catches do provide an index of interannual variation. This is especially valuable if the entire migration period is bracketed by the period of fish wheel operation (for example, as with pink salmon).

Age, length, and sex data were collected from sockeye, pink, and chum salmon caught in the fish wheels.

¹ New directed chinook fisheries have been implemented as a result of an agreement reached between the U.S. and Canada in February 2005.

OBJECTIVES

The primary goals of the Taku River sockeye salmon tagging program in 2007 were to obtain information on the above-border run size, distribution, migratory timing, and age-sex-size composition of sockeye salmon stocks in the Taku River drainage.

Specific objectives of this study were:

1. Estimate the total spawning abundance of sockeye salmon returning to Canadian portions of the Taku River with an estimated coefficient of variation no greater than 10% of the estimate. Estimate weekly inriver abundance with a coefficient of variation no greater than 20% of the estimate;
2. Estimate the age, length, and sex composition of sockeye salmon migrating past the fish wheel site on a weekly basis;
3. Forecast total abundance of sockeye salmon on a weekly basis based on tag-recovery data and historical migration-timing data;
4. Quantitatively describe the migratory timing (mean and variance) of the sockeye, pink, and chum salmon migrations past Canyon Island; and
5. Estimate the annual age and sex composition of pink and chum salmon migrating past the fish wheel site.

Objectives for the Taku River coho and chinook salmon mark-recapture studies are outlined in reports published by the Pacific Salmon Commission and/or the ADF&G Division of Sport Fish.

METHODS

Study Area Description

The Taku River originates in the Stikine plateau of northwestern British Columbia, and drains an area of approximately 17,000 square kilometres (Figure 1). The merging of two principal tributaries, the Inklin and Nakina Rivers, approximately 50 km upstream from the international border forms the Taku River. The river flows southwest from this point through the Coast Mountain Range and empties into Taku Inlet about 30 km east of Juneau, Alaska. Approximately 95% of the Taku River watershed lies within Canada.

The Taku River is turbid, with much of its discharge originating in glacial fields on the eastern slopes of the Coast Range Mountains. This turbidity precludes complete enumeration of salmon escapements in many areas by aerial or foot surveys. Water discharge in the summer generally increases in proportion to the amount of sunshine received in the interior on coastal mountain ranges (ADF&G 1955). Winter (February) flows range from approximately 40-104 m³/s at the U.S. Geological Survey water gauging station located on the lower Taku River near Canyon Island (Schellckens et al. 1996). Discharge increases in April and May and reaches a maximum average flow of 700-1,400 m³/s during June. Flow usually remains high in July and drops in late August. The efficiency of fish wheels used to capture fish for tagging and the effectiveness of the Canadian commercial fishery are affected by the magnitude of river

discharge. Sudden increases in discharge in the lower river result from the release of the glacially impounded waters of Tulsequah Lake (Kerr 1948; Marcus 1960). These floods usually occur once or twice a year between May and August. During water years 1988 to 1995 the instantaneous peak flow due to a Tulsequah event was 2,889 m³/s (August 17, 1989; Shellekens et al. 1996). During the floods, water levels fluctuate dramatically and the river carries a tremendous load of debris.

Fish Wheel Operation

Migrating adult salmon were captured with two fish wheels at Canyon Island, located approximately 4 km downstream from the international border (Figure 1). Each fish wheel consisted of two aluminum pontoons in a framework, measuring approximately 12 m in length and 6 m in width and filled with closed-cell styrofoam for flotation, supporting an axle, paddle, and basket assembly. Two fish-catching baskets were rotated about the axle by the force of the water current against the baskets and/or paddles. As the fish wheel baskets rotated, they scooped up salmon. V-shaped slides attached to the rib structure of each basket directed fish to aluminum liveboxes bolted to the outer sides of the pontoons.

The fish wheels were positioned in the vicinity of Canyon Island on opposite riverbanks, approximately 200 m apart, and have been operated in identical locations since 1984. They were secured in position by anchoring to large trees with 0.95 cm steel cable and were held out from, and parallel to, the shoreline by log booms. The Taku River channel at this location is ideal for fish wheel operation. The river is fully channelized through a relatively narrow canyon that has very steep walls.

The fish wheels rotated at 0-4 r.p.m., depending on the water velocity and the number of attached paddles. When water levels subsided, more paddles were attached and the fish wheels were moved farther out from shore into faster water currents to maintain a speed of basket rotation adequate to catch fish.

Over time it has become clear that Tulsequah River floods are preceded by a sudden decline in river temperature and a corresponding rapid increase in river level. It is standard operating procedure to stop the fish wheels when river levels near 290 cm (114 inches, standardized gauge measure). By doing so, damage to the fish wheels is minimized and significant labour and material costs avoided.

Baskets and liveboxes are removed from the pontoons and stored on high ground during the off season. The pontoons are towed upstream to a backwater slough and securely moored during the off season.

Tagging and Sampling Procedures

All sockeye captured in the fish wheels were sampled for sex and mid-eye to fork of tail length (MEF). In addition, a sub-sample of 260 sockeye salmon per week were sampled for scales. Cliethral arch to fork of tail (CAF) length measurements were taken from 200 sockeye salmon throughout the season, and paired with MEF measurements. Canadian fish buyers prefer a headless, gutted product; because of this, the only length measurement available from the commercial fishery was CAF. The paired MEF and CAF measurements from the fish wheels allow conversion of CAF measurements to MEF.

All chum salmon were sampled for sex, scales, and MEF length. The daily sampling goal for pink salmon was 25 fish; these fish were sampled for sex and MEF length.

All uninjured sockeye greater than 350 mm (MEF length) were tagged with numbered spaghetti tags. Sockeye less than 350 mm (MEF) were not tagged because fish in this size range are virtually unsuceptible to capture in the upriver gillnet fishery from which tagged to untagged ratios are used to

develop population estimates for these species. Sockeye salmon with serious wounds (most often thought to be seal inflicted) were not tagged. Pink, chum and steelhead salmon were not tagged.

Salmon were dipnetted from the fish wheel liveboxes into a tagging trough partially filled with river water. Spaghetti tags (Floy Tag and Manufacturing Inc., Seattle, WA)² were applied to sockeye salmon as follows: one person held the fish in the tagging trough while a second person inserted a 15 cm applicator needle and attached spaghetti tag through the dorsal musculature immediately below the dorsal fin. The ends of the spaghetti tag were then knotted together with a single overhand hitch. Biological sampling was also conducted during application of the spaghetti tags. Sex and length measurements were recorded, and scale samples taken from all chum salmon, and sub-samples of the sockeye salmon caught. Sex and length data were also collected daily from a sub-sample of 25 pink salmon, but scales were not taken from this species. The tagging and sampling procedures took from 40 to 60 seconds per fish to complete. The fish were then immediately and gently released back into the river.

The spaghetti tags used for sockeye salmon were made of hollow fluorescent orange PVC tubing (approximately 2.0 mm in diameter and 30 cm in length) and were consecutively numbered and labeled with project description information.

In general, fish wheel catches were sampled in the morning, afternoon, and evening. Less frequent checks, morning and evening, were made during lulls in the migration to minimize crew overtime. During peak migration times catches were sampled more frequently, early in the morning and late at night.

Tag Recovery

Sockeye were inspected for tags in Canadian commercial, test, and aboriginal ("food fish") fisheries, which occurred in Canadian portions of the Taku River within 20 km of the international border. All sockeye salmon caught in the commercial, test and lower river aboriginal fisheries were considered to have been examined for tags and all of the captured tags were considered to have been recovered.

The commercial fishery was open from one to seven days per week from April 30 to October 5. Chinook salmon were targeted until mid-June; sockeye salmon from then until mid-August; and finally coho salmon for the remainder of the season. Test fisheries were conducted from May 3 to June 17 and then from September 2 to October 5 targeting chinook and coho salmon, respectively. Drift and set gillnets were the gear types used; mesh sizes ranged from 15 cm (5 1/2 inches) to 20.4 cm (8 inches) with the mesh size of 15 cm predominating during the sockeye season.

Daily tag return was a condition of the Canadian commercial licence. As an additional incentive, a cash reward of \$5.00 (Canadian) was offered by DFO for each sockeye tag returned from any fishery (i.e. commercial, aboriginal, or test fishery). Canadian catch statistics and tags were collected daily during fishery openings by DFO personnel stationed at Ericksen Slough, just upstream of the Tulsequah River. Catch statistics were communicated to the DFO office in Whitehorse via satellite telephone and then relayed to the ADF&G office in Juneau. ADF&G offered a \$2.00 (U.S.) reward for each tag returned from the District 111 and the inriver personal use fisheries. Tag observations and recoveries were also made at enumeration weirs located at Kuthai, King Salmon, Little Trapper, and Tatsamenie lakes. Additional recoveries were made on directed sampling excursions to the Nahlin River and mainstem Taku River spawning grounds.

Sex, length, and scale data were obtained from these locations as well as the commercial and test fisheries.

² Mention of trade names does not constitute endorsement by DFO or ADF&G.

Tagging and tag recovery data were organized by statistical week for analysis. Statistical weeks begin at 00:01 AM Sunday and end the following Saturday at midnight, with weeks being numbered sequentially beginning with the week encompassing the first Saturday in January. Inclusive dates for 2006 statistical weeks are shown in Appendix A.

Statistical Methods

Sockeye salmon tagging data, tag recovery data and catch data were entered into an abundance estimation program which is referred to as the Stratified Population Analysis System (SPAS) (Amason et al. 1996). This model provides stratified population estimates using maximum likelihood techniques (Plante 1990) and associated variances when s (the number of tagging stratum) and t (number of recovery stratum) are not equal. For cases in which $s=t$, the model provides stratified population estimates based on Chapman and Junge (1956) and Darroch (1961). This stratified method was used because it allows the probabilities of capture in tagging and recovery strata to vary across the strata.

Assumptions necessary to form consistent (i.e., approaching unbiased as sample size increases) stratified mark-recapture estimates in this study include (Amason, et al. 1996):

1. All fish that pass Canyon Island during the period of interest have a non-zero probability of recovery in the commercial fishery and all fish caught by the fishery have a non-zero probability of being tagged (i.e., the population is closed);
2. There is no tag loss, tag induced mortality, tag mis-identification or non-reporting. Should any of these occur, they are to be estimated and adjusted for;
3. All fish, tagged or not, are independently caught with the same probability in any given recovery stratum;
4. All fish, tagged or not, move from a given release stratum to the recovery strata independently with the same probability distribution; and
5. There are no release strata or recovery strata where no tags are released or found respectively, and there are no rows or columns of the release-recovery matrix which are linear combinations of other rows or columns respectively.

The first assumption is addressed by the fact that two fish wheels are used in a consistent manner throughout the season and that the inriver fishery is conducted weekly. For the second assumption, tag-induced mortality was shown to be insignificant in a holding study conducted by McGregor and Milligan (1991, unpublished data). The extent of tag loss by shedding, misidentification, or non-reporting, was also found to be negligible in that study and several subsequent ones (e.g. Kelley et al., 1997). The third and fourth assumptions have not been assessed, while the fifth assumption is met by pooling of various recovery or release strata.

Inriver sockeye salmon run estimates were generated on an inseason basis in 2007. Mark-recapture data was forwarded to the Juneau ADF&G and Whitehorse DFO offices after each day of the commercial fishery. Data was analyzed and inriver abundance estimates were developed. Historical migratory timing data was then used each week to project the total inriver run size for the season. Due to the estimated three to four days travel time for fish between the Taku Inlet gillnet fishery and Canyon Island (Clark et al. 1986), as well as between Canyon Island and the Canadian fishery (based on current year tag recovery

data), our estimates of inriver abundance corresponds with the movement of Taku River sockeye salmon through District III approximately one to two weeks earlier.

Fishery management decisions that affect the magnitude and distribution of harvests and escapements are based in principle on the measured or perceived abundance of fish through time. Mundy (1982) described a set of statistics, termed migratory timing statistics, useful for characterizing the annual timing of fish migrations and for comparing the timing of migrations between years. Abundance per unit of time is divided by the total abundance throughout the migration to generate a time series of proportions, or time density. The shape of the time density characterizes the timing and temporal distribution of the migration. Two simple features of the time density are the mean date and variance or dispersion of the migration through time. We used fish wheel CPUE as an index of the abundance of fish migrating past Canyon Island, and calculated migratory timing statistics following the procedures of Mundy (1982). The mean date of passage in a migration of m days was estimated by:

$$\bar{t} = \sum_{t=1}^m t * P_t \quad , \quad (1)$$

where \bar{t} was the mean day of the migration ($t=1$ was the first day of the migration and m was the last day), and P_t is the proportion of the total cumulative fish wheel CPUE that occurred on day t . The calculated mean date is reported as the corresponding calendar date.

The variance of the migrations was estimated by:

$$s_t^2 = \sum_{t=1}^m (t - \bar{t})^2 * P_t \quad , \quad (2)$$

The timing of individual sockeye salmon stocks past Canyon Island was derived from recoveries of tagged fish on the spawning grounds and was weighted by fish wheel CPUE to permit the escapement of a particular stock to be apportioned to week of passage past Canyon Island. The formula we used for determining the proportion of the run occurring each week for each stock was:

$$\frac{C_k * T_{ks}}{T_k - T_{kc}} \quad , \quad (3)$$

$$\sum_{j=22}^{38} \frac{C_k * T_{kj}}{T_K - T_{kc}}$$

where: k is the statistical week of interest; C_k is the weekly proportion of the total season's fish wheel CPUE, T_{ks} is the number of spawning ground recoveries of stock s that were tagged in week k , T_k is the number of fish tagged at Canyon Island in statistical week k , and T_{kc} is the number of fish tagged at Canyon Island in statistical week k and caught in the Canadian fishery.

An assumption implicit in this calculation is that the removal of fish by the Canadian inriver fishery does not alter the migratory timing distribution of individual stocks. This assumption may be violated because the Canadian fishery harvest rate of the inriver run varied between fishing periods.

RESULTS

Fish Wheel Operation

Fish wheels were operated on the Taku River from May 18 through September 30. Fish wheel I, located furthest upriver, was installed on May 18; fish wheel II was installed on May 19. Additional details regarding operations are presented in Appendix B.1

The aluminum two-basket configuration first used in 1996 has proven to be effective at very low river levels (as measured on a permanent staff gauge).³

Fish Wheel Catches

Daily catches of sockeye, pink, and chum salmon in the Canyon Island fish wheels are listed in Appendices B.1. Dates of operation and the total fish wheel catch by species for the 1984 to 2007 period are presented in Table 1. Graphs of the fish wheel CPUE for sockeye, pink, and chum salmon are included in Figure 3.

The catch of sockeye salmon in the Canyon Island fish wheels in 2007 was 7,664. The total catch was 42.1% above the 1997 to 2006 average (Table 1; Appendix B.1). Fish wheel catches occurred from June 10 through September 28, and peaked during statistical week 31 (July 29 through August 4), when 2,529 sockeye salmon were captured. Prior to the first Canadian directed sockeye commercial fishery opening on June 17 (statistical week 25), only 4 sockeye salmon had been captured in the fish wheels (Appendix B.1). As in past years, the daily catches fluctuated dramatically. The effects of the U.S. commercial fishery in Taku Inlet were observable as fish wheel catches declined to their lowest levels between Thursday and Saturday weekly; this suggested that the average travel time between Taku Inlet and Canyon Island was three to four days.

The total 2007 pink salmon catch in the fish wheels at Canyon Island was 12,405 (Table 1; Appendix B.1), 8.9% below the 1997 to 2006 average. The peak daily catch of pink salmon in 2007 (1,685 fish) occurred on July 26. The 2007 fish wheel catch of chum salmon was 462. The total catch was 48.7% below the 1997 to 2006 average of 311. The peak daily catch of chum salmon (50 fish) occurred on September 13 (Appendix B.1). The total fish wheel catch of steelhead and Dolly Varden in 2007 were 63 and 425 fish respectively. The steelhead catch was 54.3% below the 1997 to 2006 average of 116. The total catch of 425 Dolly Varden was 44.1% above the 1997 to 2006 average.

Tagging and Recovery Data

Of the 7,664 sockeye salmon caught in the Taku fish wheels, 7,055 were tagged (92.1%). Only jack sockeye salmon (fish smaller than approximately 350 mm MEF that have spent only one year at sea) or sockeye with noticeable injuries were not tagged. Daily numbers of sockeye caught and tagged are listed in Appendix B.1. Recoveries downstream (U.S. personal use and D-111 fishery) of Canyon Island totaled 19 (0.008% of tags applied), leaving 7,036 available for recapture in Canadian fisheries. The Canadian commercial fishery recaptured 1,320 tagged sockeye and accounted for 54.0% of the total sockeye tags recovered or observed in upstream fisheries (Table 2). The Canadian test fishery

³ The aluminum baskets were experimentally used in 1996. Previous programs were constrained by low water conditions, particularly in the fall, which would not effectively turn the fish wheels.

recovered 11 tags (.005%) and the aboriginal fishery recovered 6 tags (0.002%). Tags were also observed in terminal areas, principally Little Trapper and Tatsamenie lakes; these numbered 331 and 754 respectively. Only one tag was observed at King Salmon Lake, and none was observed at Kuthai Lake. Sockeye salmon weir counts at these locations were 7,153, 11,187, 5 and 204 sockeye respectively. It is believed that the King Salmon and Kuthai counts are not representative of stock strength, as high water conditions may have delayed or prevented fish from reaching their destinations; at King Salmon Lake, several hundred sockeye salmon were observed in September, after the weir had been removed.

Escapement Estimates

Ratios of tagged to untagged sockeye salmon in the Canadian commercial, test and catch-and-release gillnet fisheries were used to estimate the magnitude of the inriver run of sockeye salmon that passed Canyon Island during the period of June 10 to September 22, 2007. Fishwheel CPUE for sockeye was used to expand the inriver run estimate for periods of low tag recovery and effort (SW 24 and 39).

A total of 1,337 tags with corresponding recovery date information were returned from 16,714 sockeye salmon examined in the Canadian fisheries (Table 3). Tagging data from statistical weeks 24 through 25 (June 10 through June 23) and 36 through 37 (September 2 through September 15) were pooled due to low tag recovery numbers. Recovery data from statistical weeks 25 through 26 (June 17 through June 30), weeks 29 through 31 (July 15 through August 4), and weeks 35 through 38 (August 26 through September 22) were pooled due to statistically similar tagging ratios and low fishery effort. Tagging and recovery data were grouped into 12 and 8 strata, respectively (Table 4).

Using a maximum likelihood Darroch estimator, we estimated that 104,815 sockeye salmon passed Canyon Island between June 10 and September 22. The approximate 95% confidence interval associated with this estimate is 97,171 to 112,444 fish. To estimate the total run of sockeye salmon that passed before and after the period of the mark-recapture estimate, the estimate was expanded by using fish wheel CPUE. Using this method, it was estimated that 197 additional sockeye passed Canyon Island during statistical weeks 24 and 39. Downriver of the U.S./Canadian border, the U.S. inriver personal use fishery catch was estimated at 566 sockeye using a tag return expansion method based on the current inriver commercial marked fraction (3.3%). The total estimate of sockeye salmon run migrating past Canyon Island was 105,012. This estimate is 24.6% below that the 1997 to 2006 average (137,465) sockeye salmon; Table 5; Figure 4).

The Taku River sockeye salmon run above Canyon Island was exploited by the Canadian fisheries at an estimated rate of 16.3%, compared to a 1997-2006 average of 19.8% (range 12.8% to 25.5%; Table 5). After removal of 16,714, 159, and 376 sockeye salmon by the Canadian commercial, aboriginal and test fisheries respectively from the estimated escapement to the Canada/U.S. border, the spawning escapement totaled an estimated 87,604 fish (Table 4). This is 20.5% below the 1997-2006 average of 110,177 sockeye salmon.

The escapement estimate does not include two groups of sockeye salmon that spawn in the drainage: (1) fish that spawn in streams located downriver from Canyon Island, and (2) jack sockeye salmon. The number of sockeye salmon spawning downstream from Canyon Island is unknown but presumed to be small; spawning has been observed annually in lower tributaries of the lower Taku River (i.e. Fish Creek, Sockeye Creek, and Yehring Creek) during annual aerial and foot surveys (McGregor, personal communication; Figure 1). The contribution of jacks can represent a sizable portion of the Taku River run; the contribution of jack (one ocean) sockeye salmon to the Canyon Island fish wheel catches from 1983 to 2006 averaged 3.9% (range 0.0 to 9.1%; Table 6). However, in 2007 the contribution of jacks was only 0.9%.

A necessary assumption of the population estimation technique used is that all fish in a particular recovery stratum, whether tagged or untagged, have the same capture probability. A factor that could violate this assumption is that tagging and recapture gear are selective for different sized fish. Based on length frequency distributions of sockeye salmon tagged at the fish wheels and of tagged sockeye recovered in the commercial fishery it is clear that the fish wheels tend to capture a higher proportion of smaller fish or the fishery captures a higher percentage of large fish (Figure 5).

In past years (Kelley et al. 1996, McGregor et al. 1991) the possible effects of size selectivity on the sockeye salmon population estimate were assessed by stratifying tagging and recovery data by size class. Results for those years demonstrate that the mark-recapture estimates are robust in respect to fish length differences between the tagging and recapture events. The summed abundance estimates obtained for large and small sockeye salmon separately were not significantly different than the pooled estimates. As a result of those findings, the 2007 mark-recapture data was not examined by fish size.

Migratory Timing

The mean date (July 29) of the sockeye salmon migration in 2007 was significantly later (9 days) than the 1997-2006 average (Table 7). The standard deviation was less than average (16.6 days in 2007 versus an average of 18.8 days); meaning the run was more compressed than typical. Migratory timing statistics (mean date July 26; standard deviation 8.4 days) showed the pink salmon run timing was six days later than average and slightly less compressed. The migratory timing relative to average for chum salmon is more difficult to assess because the duration of fish wheel operations has varied between years and has failed to cover the complete migration of this species. Assuming fish wheel CPUE in 2007 was reflective of the run, the mean date of migration was September 7 (standard deviation 10.7 days). However, it is likely that this assumption was not completely valid as there were still a small number of chum being caught at the time of fish wheel demobilization.

Sockeye Salmon Stock Timing

The timing of two individual stock groups of sockeye salmon past Canyon Island in 2007 was determined using recoveries of tagged fish from enumeration weirs (Table 8; Figure 6). These were weirs on the outlet streams of Little Trapper (232 tags) and Tatsamenie (586 tags) lakes. It was not possible to determine the timing of Kuthai Lake and King Salmon Lake stocks in 2007 due to a lack of tag recoveries.

Little Trapper Lake sockeye salmon peaked during stat week 31, July 29 through August 4. They were present at Canyon Island during statistical weeks 25 to 33 (June 17 to August 18).

Tagged fish bound for Tatsamenie Lake were present at Canyon Island between statistical weeks 27 to 37 (July 1 to September 15), however the majority of the run passed by relatively quickly. The peak week of migration for Tatsamenie Lake sockeye matched that of Little Trapper sockeye (statistical week 31).

Inriver Sockeye Salmon Migration Rates

Inriver travel times of two lake stocks could be determined from the recovery of tagged fish at enumeration weirs as described in the previous section (Table 9). Inriver travel times from Canyon Island for the Little Trapper Lake and Tatsamenie Lake stocks are shown in Figure 7. Travel times

averaged 31.7 and 31.6 days for each of these respective stocks.

Migration rates generally increased over the course of the run. Little Trapper Lake fish tagged in statistical week 26 averaged 49.3 days in transit while those tagged in statistical week 33 averaged 24.0 days. For the Tatsamenie stock, fish tagged in statistical week 29 averaged 39.0 days in transit while fish tagged in statistical week 37 averaged 22.1 days.

Age, Length, and Sex Composition

The age and sex compositions, by sex and time period, of the Canyon Island fish wheel catches of sockeye and chum salmon in 2007 are presented in Appendices C.1 and C.2. Age summaries are presented in Tables 6 and 11 while length at age summaries are presented in Tables 10 and 12.

For sockeye salmon, age 1.2 fish were most prevalent (39.2%) with age 1.3 fish comprising 36.6%, age 2.2 3.2%, age 0.2 7.7%, age 2.3 3.9%, age 0.3 8.3%, and very small numbers of age-0.1, 0.4, 1.1, 2.1, and 1.4 fish (Table 6). As identified in Table 10, the lengths of age 1.2 and 1.3 sockeye salmon (49.9 and 58.5 respectively) were slightly greater than the 1997 to 2006 averages (48.8 and 57.6 respectively). Females comprised 55.0% of the fish wheel catch of sockeye salmon (Appendix C.1).

Fish wheel catches of chum salmon were primarily comprised of age-0.3 (54.1%) fish, which is lower than the 1997-2006 average of 59.6% (Table 11). Age-0.4 fish constituted 42.4% of the fish wheel catch, lower than the 38.7% average. Female chum salmon were more prevalent (57.0%) than males (Appendix C.2). The average lengths at age for chum salmon passing Canyon Island were 581, 633, and 669 mm (MEF) for age 0.2, 0.3, and 0.4 fish respectively; in comparison, the 1997 to 2006 averages were 602, 637, and 666 respectively (Table 12).

DISCUSSION

The accuracy of mark-recapture studies in providing estimates of abundance is dependent on the degree to which the underlying assumptions of the analytical methods used are satisfied. We have chosen to use a stratified Darroch type estimator for our Taku River sockeye abundance estimates because we have different capture probabilities in the tagging and recovery strata due, primarily, to fluctuations in river level. In estimating the abundance of adult sockeye salmon in the Taku River we assumed: (a) tagging of adult sockeye salmon was in proportion to their numbers immigrating over time; (b) no sockeye salmon entered or left the system between the tagging and recovery events or sockeye salmon that made up the population of the capture strata have a non-zero probability of recapture during the recovery event; (c) no tag-induced mortality occurred; (d) the probability of recovering sockeye salmon is independent of its tagged/untagged status. Assumptions underlying this model, outlined above, have been examined at various times during the course of this project (Kelley et al. 1997, McGregor et al. 1991).

With respect to assumption (a), tagging efforts at the Taku River fish wheels and recovery efforts in the Canadian fisheries were conducted on a frequent basis through the season. Both of the fish wheels were strictly maintained and adjusted throughout the entire sockeye salmon run. The wheels operated 24-hours per day except during equipment breakdowns; however it is known that river conditions affect the fishing efficiencies of both wheels. Recovery efforts were conducted a minimum of two days per week throughout the season, but water conditions can also affect the efficiency of commercial and test fishery set and drift nets. We are able to work around these variations in gear efficiency by using the Darroch stratified estimator for generating abundance estimates; this allows the probabilities of capture in tagging and recovery strata to vary across time but not within strata.

It was likely that assumption (b) was violated in recent years of the Taku sockeye mark-recapture program because there were significant differences in the cumulative distribution function of length between fish sampled at the fish wheels and at the recovery location (Figure 5). Smaller fish were more prevalent in fish wheel samples than in the recovery samples. Stratification of mark-recapture data by size would remove possible bias in population estimates caused by differences in capture probabilities due to fish size (Bernard and Hansen 1992). In past studies, summed abundance estimates obtained for large and small sockeye salmon were not significantly different than the pooled estimates (Andel and Boyce, 2009). Based on those results the mark-recapture data for 2007 was not examined by fish size. We were able to make some correction for this possible bias by completely removing smaller "jack" salmon (less than or equal to 360 mm MEF length) from tag and recovery data.

We were able to assess the short-term loss of tags caused by physical breakage or shedding. Fish that lose their spaghetti tags are readily identifiable by the presence of entrance and exit holes just below the dorsal fin created during tag application. Those holes serve as a secondary mark. In the fish wheels, no sockeye or coho salmon were found throughout the season that had the needle hole "secondary mark" and no spaghetti tag. These results are consistent with those observed in previous years. In addition, in statistical weeks 25 through 36, over 2,089 fish were examined for tagging needle marks in the Canadian commercial fishery after tags had been removed by fishers. The number of tagging needle marks was compared with tag recovery rates, and found to be lower overall (6.0% versus 7.9%) (Appendix D). We therefore believe that breakage or shedding of tags among sockeye subjected to the inriver fishery is minimal. The close proximity of the fishery to the tagging site (4 km) results in a very short travel time between the two locations.

Fish wheels were not modified in 2007 and functioned effectively. As in recent years, a 2-basket configuration was used for the entire season.
